Most of the palato-gingival grooves (93.8%) were in maxillary lateral incisor teeth. Statistical analyses revealed no differences in groove prevalence on the basis of sex or race. Results of the study also indicate that the palato-gingival groove is associated with poorer periodontal health as measured by the GI and PDI and more plaque accumulation as measured with the PII.

Palato-gingival grooves on maxillary incisors often present a diagnostic and treatment-plan-ning dilemma. While frequently associated with periodontal pockets and bone loss, pulpal necrosis of these teeth may precipitate a combined endodontic-periodontic lesion. Developmental radicular anomalies include the palatogingival groove, the distolingual groove and the radicular groove. Developmental infoldings may result in defects that can provide a pathway for pulpal pathology, and consequently periodontal destruction. Various studies have shown different treatment approaches for this developmental anomaly.

A developmental anomaly or the presence of perio-dontal disease can cause the bone surrounding some teeth to undergo alterations that result in osseous defects. 1 For example, a palatogingival groove is an anomaly of enamel formation that predisposes the teeth to severe bony defects. 2 The palatogingival groove facilitates bacterial colonization of the gingival complex, leading to periodontal inflammation, epithelial attachment breakdown, and progression to a periodontal pocket with bone ...
